

# SPMI-CTRL

## MIPI SPMI Master or Slave Controller

The SPMI-CTRL core implements a highly featured, easy-to-use controller for the MIPI System Power Management Interface (MIPI-SPMI) bus. It supports the latest version (v2.0) of the MIPI-SPMI

specification, and is suitable for the implementation of either master or slave nodes in an SPMI bus.

The core is designed to minimize the software load on the host processor. Once configured, the core requires no assistance from the host to initialize the bus, connect to bus or disconnect from the bus, grant access of the bus, execute incoming SPMI commands, generate ACK/NACK responses, and check address and data parity.

Although the core only expects the host to provide the outgoing SPMI commands, it provides thorough status information to the host, which can be used for a higher application layer or for debugging purposes. Last received command, outgoing command status, bus status, and node operation status are made available to the host via the core's registers. Parity errors, unknown commands, or failure of receiving node to provide ACK/NACK response are also reported. Furthermore, the core can be programmed to operate in debug mode, under which the core captures and reports all SPMI bus commands regardless of the destination address.

Integration of the core is extremely simple: The core provides access to its registers via a AMBA™ 2 APB slave interface, and converts the incoming SPMI read/write commands to accesses on its AHB master port. This SPMI-AHB bridging allows easy mapping of the SPMI address space to shared memories or peripheral registers. A

dedicated interface allows integration with application specific authentication logic, which can be reduced to just hardwiring the authentication response data. The core uses separate clocks for its APB and AHB bus interfaces, and a separate reference clock source for its internal timer. Clocks are independent to each other, with clean clock domain crossing boundaries, and the only requirement is that the AMBA interface clocks have a frequency larger or equal to the maximum SPMI clock frequency.

The core is designed with industry best practices, and its reliability has been proven through rigorous verification.

### Size and Performance

The SPMI-CTRL can be mapped to any AMD FPGA device, provided sufficient resources are available. The following table provides sample performance and resource utilization data. Please contact [CAST](#) to get characterization data for your target device and technology

Configuration	Device Family	Logic Resources	Max. Serial Clock
Arbitration-Capable Master	Spartan-7, Artix-7, Kintex-7	880 LUTs	26 MHz
Arbitration-Capable Master	Kintex & Virtex Ultrascale	830 LUTs	26 MHz
Request-Capable Slave	Spartan-7, Artix-7, Kintex-7	750 LUTs	26 MHz
Request-Capable Slave	Kintex & Virtex Ultrascale	690 LUTs	26 MHz

### FEATURES

#### MIPI-SPMI v2.0 Master or Slave

- Supports High Speed (HS) and Low Speed (LS) device classes
- Serial clock frequencies from 32kHz to 26MHz
- Supports all commands, including Block, Extended and Extended Long Read/Writes
- Supports all arbitration levels. Suitable for multi-master and/or multi-slave buses
- Configurations:
  - Arbitration-Capable Master
  - Non-Arbitration-Capable Master
  - Request-Capable Slave
  - Non-Request-Capable Slave

#### Low Host Overhead

- Autonomously performs bus initialization, bus connect/disconnect, and bus arbitration
- Autonomously executes all incoming SPMI commands, and generates ACK/NACK responses
- Host is only required to: a) initialize register values after a reset b) define outgoing commands and arbitration levels and c) optionally respond to reported errors.

#### Run-time Debugging Features

- Broadcasts SPMI bus state and device state
- Detects and reports parity, bus or command errors
- Under debug mode captures all traffic in the SPMI bus
- Run-time programmable identifiers (Master, Slave and up to 6 Group Slave Identifiers per device)

#### Easy Integration

- Directly bridges SPMI and AHB bus address space, allowing SPMI address space mapping to either a shared memory or directly to peripheral registers
- Register access via 32-bit AMBA™ 2 APB bus

#### Small and Low Power

- Less than 900 LUTs for either the master or the slave core
- Direct serial clock usage to minimize switching activity when idle

#### Deliverables

- Verilog RTL or targeted netlist
- Testbench
- Sample synthesis and simulation scripts
- Comprehensive documentation
