The H16550S is a standard UART providing 100% software compatibility with the popular Texas Instruments 16550 device. It performs serial-to-parallel conversion on data originating from modems or other serial devices, and performs parallel-to-serial conversion on data from a CPU to these devices.

The H16550S can be run in either 16450-compatible character mode or in 16550-compatible FIFO mode, where an internal FIFO relieves the CPU of excessive software overhead.

Developed for easy reuse, the H16550S is available optimized for several Lattice devices, with competitive utilization and performance characteristics.

### Applications
- Serial or modem computer interface
- Serial interface within modems and other devices

### Block Diagram

![Block Diagram](image)

### Functional Description

As shown above and explained below, the H16550S includes six major blocks: Interface, Registers, RXBlock, Interrupt Control, Baud Rate Generator, and TXBlock. All inputs and outputs for the H16550S are fully synchronous to the rising edge of the CLK input.

### Interface (RWCONTROL)

The Interface block is responsible for handling the communications with the processor (or parallel) side of the system. All writing and reading of internal registers is accomplished through this block.

### Registers (UART_REG)

The Registers block holds all of the device’s internal registers. See the Register Description table for details on existing registers and their addresses. Some information comes from the other blocks, but this is all gathered together in the Registers block and made available to all blocks.

### FEATURES

- Capable of running all existing 16450 and 16550a software
- Fully Synchronous design. All inputs and outputs are based on rising edge of clock
- In FIFO mode, the transmitter and receiver are each buffered with 16 byte FIFOs to reduce the number of interrupts presented to the CPU
- Adds or deletes standard asynchronous communication bits (start, stop and parity) to or from the serial data
- Independently controlled transmit, receive, line status and data set interrupts
- Programmable baud generator divides any input clock by 1 to \((2^{16} - 1)\) and generates the \(16 \times\) clock
- Modem control functions (CTSn, RTSn, DSRn, DTRn, RIn, and DCDn)
- Fully programmable serial interface characteristics:
  - 5, 6, 7, or 8 bit characters
  - Even, odd, or no-parity bit generation and detection
  - 1, 1½, or 2 stop bit generation
  - Baud generation
- False start bit detection
- Complete status register
- Internal diagnostic capabilities: loopback controls for communications link fault isolation
- Full prioritized interrupt system controls
- Optional AMBATM APB Bus Interface
Functional Description (continued)

RXBlock
This is the receiver block. It handles the receiving of the incoming serial word. It is programmable to recognize data widths such as 5, 6, 7 or 8 bits, various parity settings such as even, odd or no parity and different stop bits of 1, 1½ and 2 bits. It checks for errors in the input data stream such as overrun errors, frame errors, parity errors and break errors. If the incoming word has no problems it is placed either in the Receiver Holding register or in the Receiver FIFO depending on the mode programmed.

Interrupt Control
The Interrupt Control block sends an interrupt signal back to the processor depending on the state of the FIFO and its received and transmitted data. There are various levels of interrupt which can be read from the Interrupt Identification register, which gives the level of interrupt. Interrupts are sent in the condition of empty transmission or receiving buffers (or FIFOs), an error in the receiving of a character, or other conditions requiring the attention of the processor.

Baud Rate Generator
This block takes the input clock, CLK, and divides it by a programmed value (from 1 to 2¹⁶ – 1). This divided clock is then divided by 16 to create the transmission clock called the Baudout clock.

TXBlock
The Transmit block handles the transmission of data written to the Transmission Holding register (or transmit FIFO). It adds required start, parity and stop bits to the data being transmitted so that the receiving device can do the proper error handling and receiving.

Component Substitution
The H16550S core is modeled after the Texas Instruments 16550, with the following differences:

- No provision is made for a crystal. The CLK input is designed to accept a standard digital input.
- The RCLK input in the Asynchronous version is replaced by CLK with rclk_enb which has the same frequency as BAUDOUTn.
- The bi-directional Data Bus has been split into an input and an output component. In order to use the core with a bi-directional Data Bus, the DDIS signal can be used as the controlling signal for the tri-state drivers.
- RD2, WR2, CS1 and CS2 have been eliminated. A single signal takes their place. These are RD, WR and CS.
- The ADSN signal has been removed. The H16550S functions as if the ADSN signal is held low. The included wrapper can be used to add the ADSN functionality latching the address and data bases.

- The main clock input CLK must be active from power-up.
- The Baudrate Generator is reset to the 0001h value upon activation of the MR signal. Programming the BRG to 0000h is an illegal value. The minimum value for the BRG is 0001h. Until the BRG is programmed, no output is generated.
- The Output Data Bus always shows the value of the last register read.

Implementation Results
The following are typical performance and utilization results using several Lattice devices.

Core Modifications
The H16550S core can be customized to include:

- Removing or changing the size of the FIFO
- Removing various control interface signals

Please contact CAST for any required modifications.

Support
The core as delivered is warranted against defects for ninety days from purchase. Thirty days of phone and email technical support are included, starting with the first interaction. Additional maintenance and support options are available.

Verification
The core has been verified through extensive synthesis, place and route, and simulation runs. It has been embedded in several shipping customer products, and is proven in both ASIC and FPGA technologies.

Deliverables
The core is available in synthesizable RTL and FPGA netlist forms, and includes everything required for successful implementation, including a sophisticated self-checking testbench, simulation scripts, test vectors, and expected results, synthesis scripts and comprehensive user documentation.
